# CATALYTIC ANODES IN ELECTROWINNING - INHIBITION OF POISONING BY MANGANESE IONS PART II - GALVANOSTATIC STUDIES RM MEYYAPPAN, P RAMACHANDRAN, K. V VENKATESWARAN and R SRINIVASAN Central Electrochemical Research Institute, Karaikudi-623 006 

#### Abstract

The deactivation of the catalytic anodes ceused by $\mathrm{Mn}^{2+}$ ion in electrowinning electrolytes has been studied under galvanostatic conditions. Gradual anode potential risa in presence of $\mathrm{Mn}^{2+}$ ion indicates the deterioration in the catalytic activity as a result of $\mathrm{MnO}_{2}$ formation on the electrode surface. The addition of soluble phosphorous or arsenic compounds is found to restrict the rise in anode potential. Current efficiency studies made for $\mathrm{MnO}_{2}$ deposition in presence of arsenic or phosphorous compound confirm the inhibiting tendency of these surtace active substances on $\mathrm{MnO}_{2}$ formation. Surface characterisation of polarised alectrodes has also been made using Scanning electron microscope.

Key words: Catalytic anodes, slectrowinning, galvanostatic studies, Inhlbltion of $\mathrm{Mn}^{2+}$.

## INTRODUCTION

In recent years there have been many attempts to reduce power consumption in the production of metals by electrowinning process. The power requirement can be decreased by effecting a reduction in the cell voltage which in turn can be reduced by decreasing the oxygen overvoltage. Considerable work has been done on the development of improved anodes for electrowinning of metals. A straight forward reduction in oxygen overpotential is being realised by the substitution of dimensionally stable anodes for the conventional lead alloy anodes. Noble metal oxides like $\mathrm{RUO}_{2}$ and $\mathrm{IrO}_{2}$ show excellent characteristics as catalysts for oxygen evolution. Excellent corrosion resistance, increased purity of the cathode product and reduced maintenance cost are some of the added advantages.

The impurities and additives present in electrowinning electrolytes impose some restriction, on the application of catalytic anodes for metal winning operations. For example, the presence of manganese in solution is deterrant for the operation of catalytic anodes as the deposition of poorly conductive manganese oxides during electrowinning process, gradually cover the surface resulting in increased cell voltage.

This paper investigates the problem of deactivation of catalytic anodes by manganese ions studied under galvanostatic conditions. The effect of certain soluble compounds of arsenic and phosphorous on the inhibition of $\mathrm{MnO}_{2}$ formation has been studied.

## EXPERIMENTAL

Valve metal support particles were degreased with trichloroethylene and impregnated with the activating solution in an amount equivalent to 1.0 wt \% Ru by weight of support particles. The impregnated particles were dried at $120^{\circ} \mathrm{C}$ and finally heated to $450^{\circ} \mathrm{C}$ for 1 hour, in an air stream. The electrocatalyst thus prepared was embedded in the surface of lead sheet to substantially cover the surface of the substrate. $\mathrm{RUO}_{2}$ film electrodes of $2 \mathrm{~cm}^{2}$ area on titanium substrate with Ru content. of $0.5 \mathrm{mg} \mathrm{cm}^{-2}$ were prepared by thermal decomposition technique. Platinum electrode of 5.2 $\mathrm{cm}^{2}$ area was exployed for current efficieney studies of $\mathrm{MnO}_{2}$ deposition. Anodic polarization studies were carried out under galvanostatic conditions in $1 \times \mathrm{H}_{2} \mathrm{SO}_{4}$ containing upto $20 \mathrm{gl}^{-1}$

Mn (II) ions at a current density of $400 \mathrm{~mA} \mathrm{~cm}^{-2}$. As(III) addition in the form of sodium meta arsenite from 0 to 600 ppm and addition of $\mathrm{P}(\mathrm{V})$ in the form of $\mathrm{H}_{3} \mathrm{PO}_{4}$ from 0 to 1000 ppm were employed. Long term polarization studies with electrodes of $45 \mathrm{~cm}^{2}$ area were carried out at a current density of $40 \mathrm{~mA} \mathrm{~cm}^{-2}$ for a period of 8 hrs . Potentials were measured against saturated calomel electrode (SCE) and converted to normaI hydrogen electrode (NHE). Seanning electren micrographs of $\mathrm{RUO}_{2}$ film electrodes polarized at $40 \mathrm{~mA} \mathrm{~cm}^{-2}$ in $\mathrm{H}_{2} \mathrm{SO}_{4}$ with and without Mn (II) and $P(V)$ have been taken.

## RESULTS AND DISCUSSION

Fig. I indicates potential-time curves for oxygen evolution of $\mathrm{RUO}_{2}$ film electrode. In presence of $\mathrm{Mn}^{2+}$ the anode potential gradually

Fig. 1 : Anode potential-time curves for oxygen evolution on $\mathrm{RUO}_{2}$ film electrode of $\mathrm{Ru} 0.5 \mathrm{mg} \mathrm{cm}^{-2}$ loading in $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ with additions of Mn(II)
increases as the catalytic surface is poisoned by $\mathrm{MnO}_{2}$ deposition. An increase of 50 mV in anode potential for a period of 8 hrs . duration was noticed. The $\mathrm{MnO}_{2}$ formation may be represented by the equation:
$\mathrm{Mn}^{2+}+2 \mathrm{H}_{2} \mathrm{O}=\mathrm{MnO}_{2}+4 \mathrm{H}^{+}+2 e \quad \mathrm{E}^{\circ}=1.23 \mathrm{~V}$
The gradual increase in the anode potential can be explained by the gradual coverage of the active coating by deposition of electrically poorly conductive manganese oxides.

The effect of $\mathrm{P}(\mathrm{V})$ and $\mathrm{As}(I I)$ on the anode potential under oxygen evolution conditions is shown in Fig. 2.

Fig. 2: Anode potential-time curves for oxygen evolution on $\mathrm{RuO}_{2}$ film slectrode of Ru $0.5 \mathrm{mg} \mathrm{cm}^{-2}$ loading in $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ containing $20 \mathrm{gl}^{-1}$ Mn(II) with additions of As(III) or P(V)

The reduction in rise of anode potential by $\mathrm{MnO}_{2}$ deposition with 200 ppm As(III) is 15 mV for 8 hrs , and it is around 30 mV for 600 ppm As (III) and $1000 \mathrm{ppm} \mathrm{P}(\mathrm{V})$ additions. The influence of arsenic and phosphorous compounds on the inhibition of $\mathrm{MnO}_{2}$ formation can be explained on the basis of preferential adsorption of these compounds on the electrode surface [1-3].

Table 1 shows current efficiency for $\mathrm{MnO}_{2}$ deposition with different amounts of $\mathrm{As}(\mathrm{III})$ additions, under the conditions of $1 \mathrm{M}_{2} \mathrm{SO}_{4}$ containing $20 \mathrm{gl}^{-1} \mathrm{Mn}(I)$ at a current density of $100 \mathrm{Am}^{-2}$; with the increase of $\mathrm{A}(\mathrm{ItI})$ addition, the current efficiency for $\mathrm{MnO}_{2}$ deposition decreases from $12.8 \%$ to $0.25 \%$.

TABLE I : Current afficiency for $\mathrm{MnO}_{2}$ deposition in $1 \mathrm{M}_{2} \mathrm{SO}_{4}$ containing $20 \mathrm{gl}^{-1}$ Mn(II) with arsenic (III) additions

As(III) addition
(ppm)

> Current efficiency for $\mathrm{MnO}_{2}$ deposition

Fig. 3 shows the scanning electron micrograph of $\mathrm{RuO}_{2}$ film electrode polarized in $1 \mathrm{M}_{2} \mathrm{SO}_{4}$ which indicates multi-layered pore free structure of $\mathrm{RuO}_{2}$. Fig. 4 is the SEM of $\mathrm{RuO}_{2}$ film electrode polarised in IM $\mathrm{H}_{2} \mathrm{SO}_{4}$ containing $20 \mathrm{gI}^{-1} \mathrm{Mn}$ (II) ions where massive crystalline deposition of $\mathrm{MnO}_{2}$ is seen. Fig. 5 is the SEM of $\mathrm{RuO}_{2}$ film electrode polarized in $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ containing $20 \mathrm{gl}^{-1} \mathrm{Mn}(\mathrm{II})+1000 \mathrm{ppm} \mathrm{P}(\mathrm{V})$. Absence of the characteristic massive crystalline structure indicates the inhibition of $\mathrm{MnO}_{2}$ formation.

Fig. 4 : SEM photograph of $\mathrm{RuO}_{2}$ film electrode polarised in $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ $+20 \mathrm{gl}^{-1} \mathrm{Mn}(11)$

## CONCLUSION

Poisoning of the catalytic anodes by $\mathrm{Mn}(\mathrm{II})$ ion in metal winning electrolyte has been studjed. Anode polarization studies under galvanostatio condition with platinum, $\mathrm{RuO}_{2} \mathrm{nim}$ electrode and $\mathrm{RuO}_{2}$ sponge electrodes indicated the inhibition of $\mathrm{MnO}_{2}$ formation by arsenic and phosphorous compounds. The inhibition may be due to preferential adsorption of these compounds on the electrode surface.

Fig. 5: SEM photograph of $\mathrm{RuO}_{2}$ film electrode polarised in $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ $+20 \mathrm{gi}^{-1} \mathrm{Mn}(\mathrm{II})+1000 \mathrm{ppm}$ P(V)
