
Specification No. 96/06. Application No 96/06, dated 19th November 1964. Complete Specification left on 18th September 1965. (Application Accepted 8th July, 1966.)

Index at acceptance—70C 5+6 [LVIII(5)], 154 A+C [XXXVII].

PROVISIONAL SPECIFICATION.

IMPROVEMENTS IN OR RELATING TO PREPARATION OF LITHOGRAPHIC ALUMINIUM PLATES.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH, RAY MARG, NEW DELHI-1, INDIA, AN INDIAN REGISTERED BODY INCORPORATED UNDER THE REGISTRATION OF SOCIETIES ACT (ACT XXI of 1860).

The following specification describes the nature of this invention:

This is an invention by BALKUNJE ANANTHA SHENOJ, RAMACHANDRA SUBRAMANIAN and SRI-NIVASA CHAKRAPANI of the CENTRAL ELECTROCHEMICAL RESEARCH INSTITUTE, KARAKUMI-3, S. I. RAILWAY, OASIS, CITIZEN. This invention relates to improvements in or relating to the method of preparation of Aluminium Lithograph.

Hitherto it has been proposed to 'grain' mechanically the zinc plates or use imported aluminum lithographs.

This is open to the objection that the grains are not uniform, the image is not fine and the processes are very costly on aluminium.

The object of this invention is to obviate these disadvantages by using a simple electrochemical technique for the preparation of aluminium lithographs with properties suitable for lithographic purposes.

To these ends, the invention broadly consists in 'graining' the aluminium plates either (1) mechanically, or (2) chemically, or (3) electrochemically and/or (1) anodically treating the 'grained' plates in an aqueous solution containing fluorides, chromates, carbonates, phosphates of sodium, potassium and/or ammonium in concentrations not exceeding 15 per cent, by total weight of solids in solution, the current maintained by an applied voltage ranging from 10 to 200 volts d.c. or a.c. or superimposed a.c. over d.c. (II) or suitably modifying the composition and operating conditions of the conventional anodizing baths namely sulphuric, chromic or nitric or phosphoric acid baths or a combination of these acids in appropriate proportions, and then making the film hydrophilic either by incorporating such substances as dextrin, glucose, starch, diazaldehyde starch, carboxy methyl cellulose with the anodizing baths or in the subsequent sealing step.

The following typical examples are given to illustrate the invention:

EXAMPLE 1.
The cleaner solution is 5 per cent. KOH or NaOH or 3 per cent. Na2C03, and 3 per cent. NaOH.

Temp 80° C.
Time of immersion: 2-5 min.
Anodizing solution containing
alkali chromate 1 to 20 g/l.
alkali carbonate 1 to 15 g/l.
Temp 40°C to 75°C.
Voltage 150 volts d.c.

EXAMPLE 2.
After cleaning as above, the aluminium plate is etched by immersion for 1-5 min. in a fluoride solution of ammonia kept at 90°C, and then anodizing in an aqueous solution containing alkaline carbonate 1 to 20 g/l.
alkali chromate 1 to 15 g/l.
alkali phosphate 1 to 20 g/l.
kept 40°C-60°C and voltage at 100-150 volts.

The following are among the main advantages of the invention:

1. The 'graining' is uniform.
2. The grain size can be controlled to any desired limit.
3. Number of impressions per plate is very high that it can be used for longer runs.
4. All the materials are indigenous.
5. It is very cheap, elegant and time consuming.
6. The finer details of the image are clear and hence the impressions are better than from zinc lithographs.
7. The lightness of aluminium makes it possible to reduce the freight charges, etc.
8. Highly resistant to atmospheric corrosion during storage and idle period.

COMPLETE SPECIFICATION.

IMPROVEMENTS IN OR RELATING TO PREPARATION OF LITHOGRAPHIC ALUMINIUM PLATES.

COUNCIL OF SCIENTIFIC & INDUSTRIAL RESEARCH, RAY MARG, NEW DELHI-1, INDIA, AN INDIAN REGISTERED BODY INCORPORATED UNDER THE REGISTRATION OF SOCIETIES ACT (ACT NO. XXI of 1860).

The following specification particularly describes and ascertains the nature of this invention and the manner in which it is to be performed.

This is an invention by Balkunje Anant Shenoj, Scientist; Ramachandra Subramanian, Senior Scientific Assistant and Srinivasa Chakrapani, Senior Laboratory Assistant, Citizens of India and employed in the Central Electrochemical Research Institute, Karakudi-3, S. I. R., India.

This invention relates to improvements in or relating to the method of surface preparation of aluminium plates for lithographic works.

Hitherto, it has been proposed to use mechanically grainy zinc plates or imported aluminium lithographs. The mechanical grainy is done in a horizontal rocking machine with a slurry of fine abrasives and a number of marbles bally for nearly one hour. Cost of such grinding operation may be Rs. 2 to 3 per plate. The grains produced are not uniform. The process is rather crude and time-consuming. Further, this process cannot be used on aluminium plates as it is open to the objection that the surface tends to develop "white spots" due to non-uniform oxidation. The process is also costly on aluminium plates than on zinc plates. For roto-printing very thin sheets of aluminium are used which cannot withstand such a drastic treatment.

Price: TWO RUPEES.
The object of this invention is to obviate these disadvantages by using a simple, chemical or electrochemical technique for the surface preparation of aluminum lithoplates with properties suitable for printing and at the same time with an eye on the economics of the technique, elegance and ease of operation.

Another object of this invention is to prevent the defects due to atmospheric oxidation of the aluminum surface and the development of white spots which makes the life of such plates short.

The present invention is based on the principle that the surface of an aluminum plate gets etched when treated chemically or electrochemically in solutions containing alkali salts, chromates, phosphates, halides producing a uniformly grained surface. This is subsequently oxidized anodically in an electrolyte containing sulfurous acid, chromic acid or phosphoric acid either individually or in combination in suitable quantities.

Accordingly the invention process for preparing lithographic aluminum plates comprises graining an aluminum plate chemically or electrochemically in an aqueous solution of alkali salts, chromates, phosphates or halides followed by anodically or etching the grained surface in an electrolyte of the following, namely, sulphuric acid, chromic acid or phosphoric acid.

By this process, the surface of the aluminum off-set lithoplate is smoothly and uniformly grained to a controlled size and depth producing a porous structure. This makes a firm binding with the dichromate-pum arabic coating. After subsequent development in the usual way, the light-hardened portion receive ink and the non-exposed portions being hydrophobic get dampened with sufficient water. The impressions produced from such a surface are true to the original even in finer details. Thus instead of other expensive plasticographic methods, after simple chemical and electrochemical treatment, aluminum plates can be used with improved results.

However, the subsequent electrochemical oxidation anodically in a suitable electrolyte under optimum conditions apart from retaining the optimum grain size and pore structure to properly absorb and retain the ink and water in the respective areas increases the mechanical hardness of the surface and is also resistant to corrosive atmosphere.

For preparing the aluminum plates according to this invention, slivers of aluminum such as the following can be used provided the surface structure of aluminum plates is homogeneous and does not contain any inclusions, i.e., free from surface defects:

- 2B 98.8 per cent. aluminum
- 33 98.2 per cent. manganese
- 57 B 2.5 per cent. magnesium 0.3 per cent. balance aluminum
- 65S 0.3 per cent. copper 1.0 per cent. magnesium 0.1 per cent. silicon 0.5 per cent. chromium 0.1 per cent. balance aluminum.

The process broadly consists in performing the operation as described hereunder. The aluminum plates supplied by the rolling mill is degreased to remove organic impurities by using a suitable organic solvent like trichloroethylene.

Then it is dip-cleaned at 25 to 35°C in a 5 to 10 per cent aqueous solution of sodium hydroxide for one to two minutes. It is then in running water and chemically etched in any one of the aqueous solutions given below:

- Alkali carbonate 1 to 4 per cent.
- Alkali carbonate 2 to 5 per cent.
- Temperature 60 to 100°C.
- Time 2 to 5 minutes.

Rinsed, followed by a dip in:
- Alkali or ammonium fluorides or acid fluo-3 to 10 per cent.
- Temperature 35 to 50°C.
- Time 1 minute.
- (b) Hydrochloric acid 10 to 20 per cent.
- Temperature 30 to 35°C.
- Time 2 to 3 minutes.
- (c) Hydrofluoric acid 5 to 10% by volume.
- Nitric acid 5 to 10 per cent.
- Temperature 35 to 40°C.
- Time 1 to 2 min.
- (d) Alkali pyrophosphates 5 to 8% by weight.
- Ammonium or alkali 1 to 2 per cent.
- Fluoride or fluorine.
- pH 2 to 3.
- Temperature 30 to 35°C.

(d) Etching can also be performed in a solution of "b" or "c" by use of alternating current with two aluminum plates connected to the current leads into the electrolyte. The concentration of the chemicals may be varied within the following limits:

- Hydrochloric acid 0.1 to 2% by vol.
- Current density 0.3 to 1.0 A/sq. in.
- Temperature 25 to 60°C.
- Hydrofluoric acid 0.2 to 0.3% by volume.
- Nitric acid 0.2 to 0.5%.
- Current density 0.3 to 1.0 A/sq. in.
- Temperature 25 to 60°C.

After thoroughly rinsing from any one of the previous steps, the plate is treated electrolytically in any one of the following solutions under suitable conditions. The plate is made anodic with a similar plate placed at a distance of 10 to 15 cm. apart as the cathode.

- Alkali carbonate 2 to 5 g/l.
- Alkali chromate 1 to 4 g/l.
- Temperature 30 to 60°C.
- Applied voltage 150 to 200 V d.c.
- Time 4 to 15 min.

The voltage is gradually and continuously raised but as quickly as possible to the required voltage. Mechanical agitation or circulation of electrolyte is essential.

- Phosphoric acid 5 to 16% by volume.
- Temperature 30 to 35°C.
- Voltage 50 V d.c.
- Time 20 min.

- Phosphoric acid 3 to 6% by volume.
- Chronic acid 3 to 6% by weight.
- Temperature 30 to 35°C.
- Current density 10 to 15 a.s.f.
- Time 20 min.

- Chronic acid 10 to 25% by weight.
- Temperature 40 to 50 V d.c.
- Temperature 50 to 65°C.
- Time 18 to 20 min.

- Sulphuric acid 10 to 20% by volume.
- Temperature 30 to 35°C.
- Current density 8 to 20 a.s.f.
- Time 10 to 20 min.

After the electrolytic treatment in any one of the said solutions under the conditions described, current is switched off, the plates are removed, thoroughly rinsed in running water and dried by warm air. The plates are again ready for further processing for printing in the usual way.

The time of treatment for one plate is about 40 to 45 min. if one plate alone is processed at a time in a tank. Depending on the capacity of the tank, the number of plates processed may be increased. Further the process is also suitable for thin sheets of aluminum in the form of rolls and can be made continuous by proper design.
The following examples are given to illustrate the invention.

**EXAMPLE I.**
Degraded with trichloroethylene.
Dip cleaned in 5 per cent. alkali solution at room temperature for two minutes.
Rinsed.
Chemically etched in an aqueous solution containing:  
Hydrofluoric acid 5% by volume  
Nitrile acid 5% by volume  
at 40°C for two minutes.
Rinsed.
Anodic treatment in a solution containing:
- Alkali chromate 1 to 3 min.
- Alkali carbonate 2 to 6 min.
- Temperature 40 to 70°C.
- Applied voltage 180 V d.c.
- Time 5 to 10 min.
Mechanical agitation.
Rinsed well.
Air dried.

**EXAMPLE II.**
Degraded in trichloroethylene.
Dip cleaned in 5% sodium hydroxide as above.
Chemically etched in 5% aqueous solution of hydrofluoric acid.
Rinsed.
Anodically treated in an aqueous solution containing:
- Chronic acid 5 to 10%  
- Voltage 50 V d.c.
- Temperature 58°C.
- Time 15 min.
Mechanical agitation.

The following are some of the advantages of this invention:
1. The "graining" is uniform.
2. The grain size can be controlled to any desired limit.
3. Number of impressions per plate is very high that it can be used for longer runs.
4. All the materials are indigenous.
5. It is way cheap, elegant and less time-consuming.
6. The finer details of the image are clear and hence the impressions are better than from zinc lithoplates.
7. The lightness of aluminium makes it possible to re-use the freight charges, etc.
8. Highly resistant to atmospheric corrosion during storage and idle period.

We claim:
1. A process for preparing lithographic aluminium plates which comprises graining an aluminium plate chemically or electrochemically in an aqueous solution of alkali salts, chromates, phosphates or halides followed by anodically oxidising the grained surface in an electrolyte containing one or more of the following, namely, sulphuric acid, chromic acid or phosphoric acid.
2. A process as claimed in Claim 1 wherein the surface of aluminium lithoplate is grained chemically or electrochemically in any one of the aqueous solutions given below under the conditions of operation mentioned against each:
   a. Alkali chromate 1 to 4%  
   Alkali carbonate 2 to 5%  
   Temperature 40 to 100°C.  
   Time 2 to 5 minutes
   rinsed, followed by a dip in Alkali or ammonium fluorides or acid fluorides 5 to 10%  
   Temperature 35 to 50°C.  
   Time 1 minute
   or b. Hydrochloric acid 10 to 20%  
   Temperature 30 to 35°C.  
   Time 2 to 3 minutes
   or c. Hydrofluoric acid 5 to 16% by volume  
   Nitric acid 5 to 16%  
   Temperature 35 to 50°C.  
   Time 1 to 2 min.
   or d. Alkali prophosphate  
   Ammonium or alkali 1 to 2%  
   Fluoride or biphosphate 
   pH 2 to 3
   Temperature 25 to 60°C.
3. A process as claimed in Claim 2 wherein etching is performed in the solution of (b) or (c) by use of altering current with two aluminium plates connected to the current leads into the electrolyte.
4. A process as claimed in any of the preceding claims wherein the concentration of the chemicals may be varied within the following limits:
   - Hydrochloric acid 0.1 to 5% by vol.
   - Hydrofluoric acid 0.2 to 0.3% by volume
   - Nitric acid 0.3 to 0.63%  
   - Current density 0.3 to 1.0 A/sq. in.
   - Temperature 25 to 60°C.
5. A process as claimed in any of the preceding claims wherein the grained plates are anodically treated in any one of the aqueous solutions given below under the conditions of operation mentioned against each:
   - Alkali carbonate 2 to 5 g/l  
   Alkali carbonate 2 to 5 g/l
   - Temperature 50 to 60°C.
   - Applied voltage 150 to 200 V d.c.
   - Time 4 to 18 min.
   The voltage is gradually and continuously raised but as quickly as possible to the required voltage, mechanical agitation or circulation of electrolyte is essential.
   or g. Phosphoric acid 5 to 10% by volume  
   Temperature 30 to 35°C.
   Voltage 50 V d.c.
   Time 20 min.
   or b. Phosphoric acid 3 to 5% by volume  
   Chronic acid 3 to 6% by weight
   Balance water
   temperature 30 to 35°C.
   Current density 10 to 15 asf
   Time 20 minutes
   or l. Chronic acid 10 to 25% by weight  
   Voltage 40 to 50 V d.c.
   Temperature 25 to 35°C
   Time 10 to 20 min.
   or j. Sulphuric acid 10 to 20% by volume  
   Temperature 30 to 35°C.
   Current density 8 to 20 asf
   Time 10 to 20 min.

6. A process for graining and anodizing the aluminium plate for lithographic work substantially as herebefore described.

7. An aluminium offset plate produced by the process as substantially described herein.
